## **APPLICATION AND LOCATION**

#### **GENERAL**

Each unit is shipped internally wired, requiring both ground-source and load-side water piping, aquastat wiring, 230/208 volt AC power wiring, and optional desuperheater piping. The equipment covered in this manual is to be installed by trained, experienced service and installation technicians.

These instructions and any instructions packaged with any separate equipment required to make up the entire heat pump system should be carefully read before beginning the installation. Note particularly any tags and/or labels attached to the equipment.

While these instructions are intended as a general recommended guide, they do not in any way supercede any national and/or local codes. Authorities having jurisdiction should be consulted before the installation is made.

#### SHIPPING DAMAGE

Upon receipt of the equipment, the carton should be checked for external signs of shipping damage. If damage is found, the receiving party must contact the last carrier immediately, preferably in writing, requesting inspection by the carrier's agent.

#### **APPLICATION**

Capacity of the unit for a proposed installation should be based on heat loss calculations made in accordance with methods of the Air Conditioning Contractors of America. The piping systems should be installed in accordance all local, state, and federal requirements, and to the references included on Page 3 of this document.

#### LOCATION

The unit may be installed in a basement, closet, or utility room provided adequate service access is ensured, and equipment will not freeze.

These units are not approved for outdoor installation and therefore must be installed inside structure being conditioned. *Do not locate in areas subject to freezing in the winter, or subject to sweating in the summer.* 

Prior to setting the unit, consider ease of piping and electrical connections for the unit. Also for units which will be used with a desuperheater, consider the proximity of the unit to the water heater or storage tank. Place the unit on a solid base, preferably concrete, to minimize undesirable noise and vibration. **DO NOT** elevate the base pan on rubber or cork vibration eliminator pads as this will permit the unit base to act like a drum, transmitting objectionable noise.

#### **ANSI Z535.5 Definitions:**

- DANGER (color RED): Indicate[s] a hazardous situation which, if not avoided, will result in death or serious injury. The signal word "DANGER" is to be limited to the most extreme situations. DANGER [signs] should not be used for property damage hazards unless personal injury risk appropriate to these levels is also involved.
- WARNING (color ORANGE): Indicate[s] a hazardous situation which, if not avoided, could result in death or serious injury. WARNING [signs] should not be used for property damage hazards unless personal injury risk appropriate to this level is also involved.
- CAUTION (color YELLOW): Indicate[s] a hazardous situation which, if not avoided, could result in minor or moderate injury. CAUTION [signs] without a safety alert symbol may be used to alert against unsafe practices that can result in property damage only.
- NOTICE (color BLUE): [this header is] preferred to address practices not related to personal injury. The safety alert symbol shall not be used with this signal word. As an alternative to "NOTICE" the word "CAUTION" without the safety alert symbol may be used to indicate a message not related to personal injury.

FAILURE TO FOLLOW THIS CAUTION MAY RESULT IN PERSONAL INJURY. USE CARE AND WEAR APPROPRIATE PROTECTIVE CLOTHING, SAFETY GLASSES AND PROTECTIVE GLOVES WHEN SERVICING UNIT AND HANDLING PARTS.

# **ACAUTION**

ALL GEOTHERMAL EQUIPMENT IS DESIGNED FOR INDOOR INSTALLATION ONLY. DO NOT INSTALL OR STORE UNIT IN A CORROSIVE ENVIRONMENT OR IN A LOCATION WHERE TEMPERATURE AND HUMIDITY ARE SUBJECT TO EXTREMES. EQUIPMENT IS NOT CERTIFIED FOR OUTDOOR APPLICATIONS. SUCH INSTALLATION WILL VOID ALL WARRANTIES.

## **NOTICE**

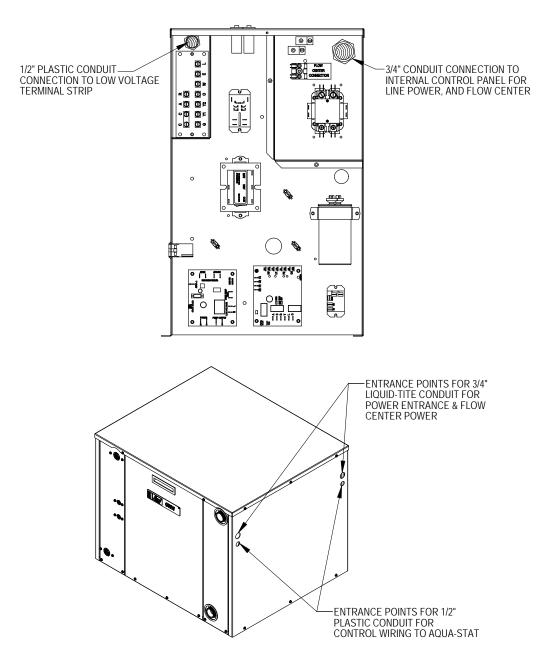

#### HIGH VOLTAGE LINE SUPPLY

Supplied with the unit is an adequate length of 3/4" liquid-tite conduit and fittings to run internally within the sheet metal chassis from the control panel to one of four (4) 11/8" holes in the chassis sides (front/rear corners) for line voltage wires to be ran through. See Figures 2A & 2B.

#### LOW VOLTAGE CONTROL WIRES

Supplied with the unit is an adequate length of  $\frac{1}{2}$ " plastic conduit and fittings to run internally within the sheet metal chassis from the low voltage box to one of four (4)  $\frac{1}{8}$ " holes in the chassis sides (front/rear corners) for thermostat wires to be ran through. See Figures 2A & 2B.

FIGURE 2A WIRE ROUTING TO CONTROL PANEL

MIS-3161

## **POWER & CONTROL WIRING**

The GW-Series Geothermal Water-to-Water Heat Pumps contain 2-stage compressors. This will need to be thought through in planning and ordering the Aquastat control.

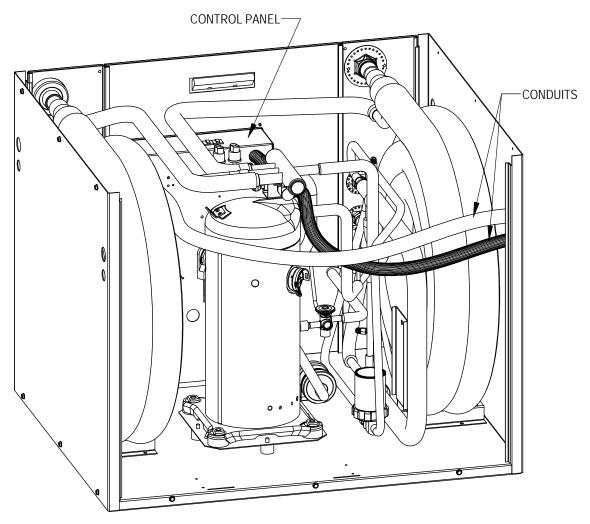

The two-stage compressor will not necessarily affect the net water temperature, but can give great benefit of reducing the required number of compressor cycles, especially under lower-load conditions.

In selecting the Aquastat, and depending upon the particular installation, there are different ways to utilize this.

1. Select an Aquastat with an outdoor temperature sensor, and program the Aquastat to only energize the "Y2" signal when outdoor temperatures fall below a certain level.

- 2. Program a length of time to offset Stage #2 being energized following Stage #1 call. This will increase system run time/thermal consistency, and minimize the start/stop cycles on the compressor, and minimize short cycling.
- 3. Program the Aquastat to only energize "Y2" when temperature of water cannot be held or increased with only "Y1" energized (only bring on "Y2" with further temperature fall).
- 4. A jumper can be installed from "Y1" to "Y2" changing the system to a single stage system. However, this is not recommended for longevity of equipment service life or energy efficiency.

## FIGURE 2B WIRE ENTRANCE CONDUITS

MIS-3162

#### **UNIT MAIN POWER WIRING**

This equipment requires a nominal 208/230-60-1 power supply for proper operation. Line voltage connections are made at the compressor contactor as noted by the wiring diagram. Unit main power will route into the control panel to the contactor through the supplied 3/4" Liquid Tite conduit from one of the four (4) selectable electrical entrance points.

#### 230/208. 1-PHASE & 3-PHASE **EQUIPMENT DUAL PRIMARY VOLTAGE TRANSFORMERS**

All Equipment leaves the factory wired on 240 Volt transformer tap. For 208 Volt operation, reconnect from 240 Volt to 208 Volt tap. The acceptable operating voltage range for the 240V and 208V transformer taps are as noted in Table 4.

TABLE 4 **OPERATING VOLTAGE RANGE** 

TAP	RANGE
240V	253 - 216
208V	220 - 187

**NOTE**: The voltage should be measured at the field power connection point in the unit, and while the unit is operating at full load (maximum amperage operating conditions).

For low voltage connections between the Aquastat and the geothermal heat pump, a low voltage terminal strip is factory mounted in the heat pump.

#### LOW VOLTAGE CONNECTIONS

These units use a grounded 24V AC low voltage circuit.

- "R" terminal is 24 VAC hot.
- "C" terminal is 24 VAC grounded.
- "Y1" terminal is the compressor part load input.
- "Y2" terminal is the compressor full load input ("Y1" must also be energized along with "Y2").
- "O" terminal is the reversing valve input. The reversing valve must be energized for cooling mode.
- "A" terminal is 24 VAC output to external flow center control, or to source water solenoid coil.
- "L" terminal is compressor lockout **output**. This terminal is activated on a high pressure, low pressure, or flow switch trip on the Geothermal Logic Control. This is a 24 VAC output.

LOW VOLTAGE CONNECTION	ONS FOR DDC CONTROLS
Heating Part Load	Energize "Y1"
Heating Full Load	Energize "Y1", "Y2"
Cooling Part Load	Energize "Y1", "O"
Cooling Full Load	Energize "Y1", "Y2", "O"

## **PIPING ACCESS TO UNIT**

Water Piping to and from the unit enters the unit cabinet on either the front or rear-side through the ability to relocate the control panel. See Figure 3 of the cabinet.

**LOOP CONNECTIONS** are a special double o-ring fitting with a retainer nut that secures it in place. (It is the same style of fitting used for the flow center connection on ground loop applications.)

**NOTE**: All double o-ring fittings require "hand tightening only". Do not use a wrench or pliers as retainer nut can be damaged with excessive force.

**NOTE:** Apply provided petroleum jelly to o-rings to prevent damage and to aid in insertion.

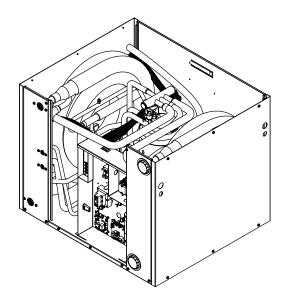

Various fittings are available so you may then connect to the unit with various materials and methods. These methods include 1" barbed fitting (straight and 90°), 1" MPT (straight and 90°), and 1-14" hot fusion fitting (straight only). See Product Specification Sheet.

**LOAD CONNECTIONS** are standard 1" Female Pipe Thread allowing for any standard 1" Male Pipe Threaded fittings to be utilized to make the connection.

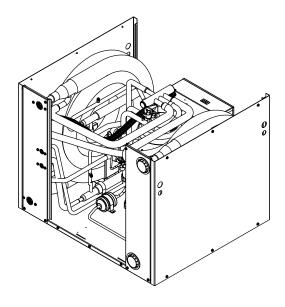

**DESUPERHEATER CONNECTIONS** are standard ½" Female Pipe Thread allowing for any standard ½" Male Pipe Threaded fittings to be utilized to make the connection.

# FIGURE 3 CHANGING WATER ENTRANCE LOCATION (FRONT TO REAR) BY RELOCATING CONTROL PANEL

**CONTROL PANEL LOCATIONS** 

FRONT - AS SHIPPED LOCATION

OPTIONAL REAR LOCATION

MIS-3163

## LOAD SIDE WATER CONNECTIONS

The use of a buffer tank is highly recommended on the load side of the GW-Series Water-to-Water heat pumps. If heat pump sizing at all the various conditions is not perfectly matched to the load, you are likely to short cycle the refrigerant system on high or low pressure controls. Buffer tanks provide thermal mass that allows the rate of generation by the heat source to be significantly different from the rate of dissipation by the distribution system. They are an essential component in any hydronic system that uses a low thermal mass on/off heat source in combination with a multiple-zone application.

#### SIZING BUFFER TANKS FOR ZONED SYSTEMS

The required volume of a buffer tank depends on the rate of heat input and release, as well as the allowed temperature rise of the tank from when the heat source is turned on, to when it is turned off. The greater the tanks volume, and the wide the operating temperature differential, the longer the heat source cycle length.

The following fomula can be used to calculate the volume necessary when given a specified minimum heat source ontime, tank operating differential, and rate of heat transfer:

$$v = \frac{\text{t x Qheatsource}}{500 \text{ x } \triangle T}$$

Where:

v = required volume of the buffer tank (gallons)

t = desired duration of the heat source's "on cycle" (minutes)

Qheatsource = heat output rate of the heat source (Btu/h)

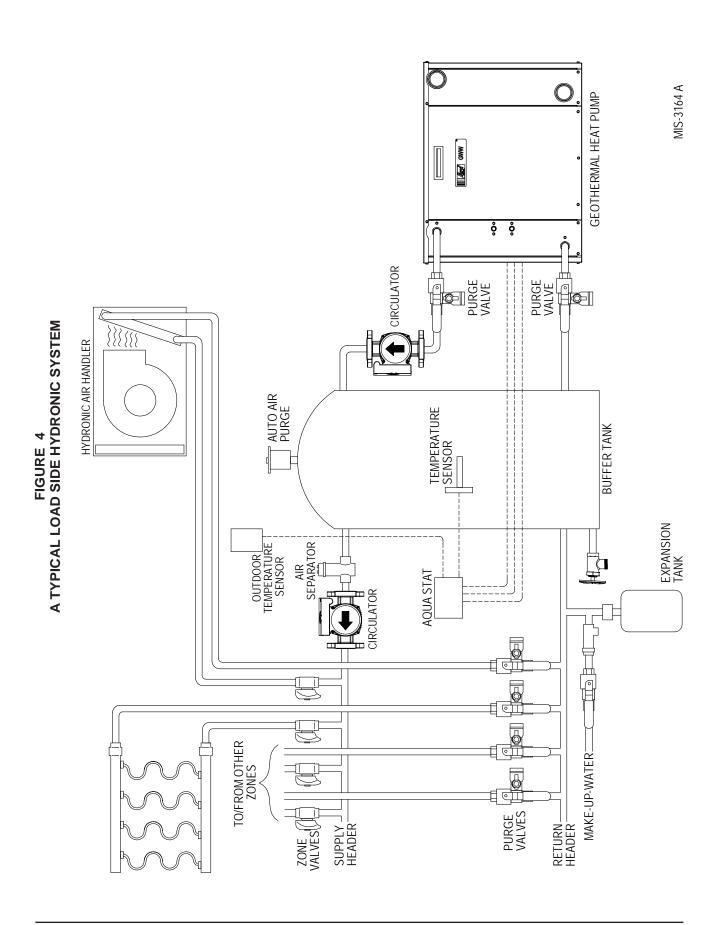

Qload = rate of heat extraction from the tank (Btu/h)

 $\Delta T$  = temperature rise of the tank from when the heat source is turned on to when it is turned off (°F).

For example, assume it's desired that a heat pump operates with a minimum compressor on-cycle duration of 10 minutes. The heat pump, when on, supplies 50,000 Btu/h. The compressor turns on when the buffer tank drops to 100°F, and off when the tank reaches 120°F. What is the necessary buffer tank volume to accomplish this?

If a tank larger than the minimum required volume is used, the on-cycle length could be increased, or the temperature differential setpoint could be reduced

The wider the temperature differential, and the greater the volume of the tank, the longer the heat source on-cycle will

## **GROUND LOOP (EARTH COUPLED WATER LOOP APPLICATIONS)**

NOTE: Unit shipped from factory with 75 PSIG low pressure switch wired into control circuit and must be rewired to 55 PSIG low pressure switch for ground loop applications. This unit is designed to work on earth coupled water loop systems, however, these systems operate at entering water (without antifreeze) temperature with pressures well below the pressures normally experienced in water well systems.

#### THE CIRCULATION SYSTEM DESIGN

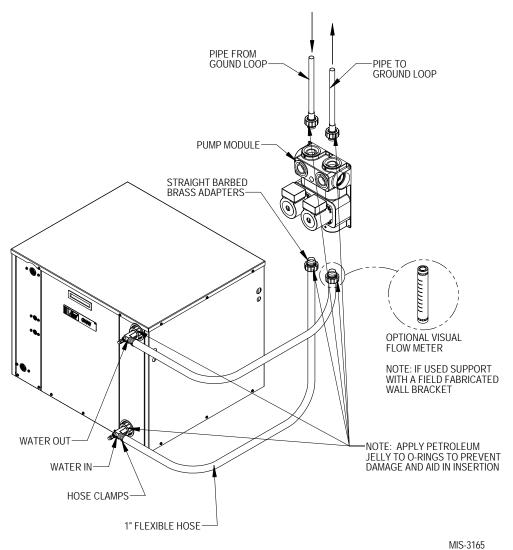

Equipment room piping design is based on years of experience with earth coupled heat pump systems. The design eliminates most causes of system failure.

The heat pump itself is rarely the cause. Most problems occur because designers and installers forget that a ground loop "earth coupled" heat pump system is NOT like a household plumbing system.

Most household water systems have more than enough water pressure either from the well pump or the municipal water system to overcome the pressure of head loss in ½ inch or ¾ inch household plumbing. A closed loop earth coupled heat pump system however, is separated from the pressure of the household supply and relies on a small, low wattage pump to circulate the water and antifreeze solution through the earth coupled heat pump and equipment room components.

The small circulator keeps the operating costs of the system to a minimum. However, the performance of the circulator MUST be closely matched with the pressure head loss of the entire system in order to provide the required flow through the heat pump. Insufficient flow through the heat exchanger is one of the most common causes of system failure. Proper system piping design and circulator selection will eliminate the problem.

FIGURE 5
CIRCULATOR SYSTEM DESIGN

#### FIGURE 6A

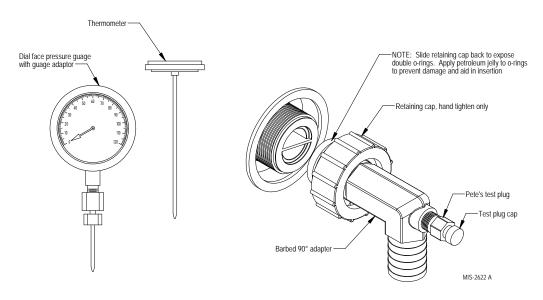

FIGURE 6B
PERFORMANCE MODEL DORFC-1 FLOW CENTER

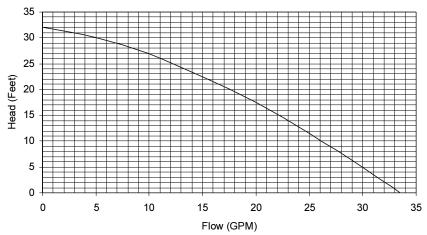

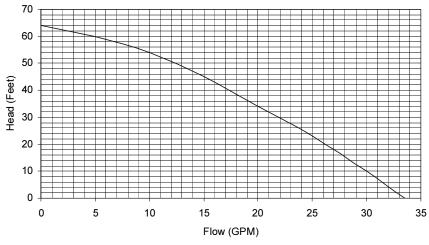

FIGURE 6C PERFORMANCE MODEL DORFC-2 FLOW CENTER

NOTE: It is highly recommended on ground water systems (pump & dump) that a cupronickel coaxial coil is utilized on the source side of the system. Not doing so, may void the product warranty due to aggressive/corrosive/highly oxygenated water attacking the copper coaxial water coil.

NOTE: Unit shipped from factory with 75 PSIG low pressure switch wired into control circuit for ground water applications.

#### WATER CONNECTIONS

It is very important that an adequate supply of clean, non-corrosive water at the proper pressure be provided before installation is made. Insufficient water, in the heating mode for example, will cause the low pressure switch to trip, shutting down the heat pump. In assessing the capacity of the water system, it is advisable that the complete water system be evaluated to prevent possible lack of water or water pressure at various household fixtures whenever the heat pump turns on. All plumbing to and from the unit is to be installed in accordance with local plumbing codes. The use of plastic pipe, where pemissible, is recommended to prevent electrolytic corrosion of the water pipe. Because of the relatively cold temperatures encountered with well water, it is strongly recommended that the water lines connecting the unit be insulated to prevent water droplets from condensing on the pipe surface.

Refer to piping, Figure 7. Slow open/close <u>Electrically</u> <u>Actuated Valve</u> with *End Switch* (2), 24V, provides on/off control of the water flow to the unit. Refer to the wiring diagram for correct hookup of the valve solenoid coil.

**Constant Flow Valve** (3) provides correct flow of water to the unit regardless of variations in water pressure.

Observe the water flow direction indicated by the arrow on the side of the valve body.

*Strainer* (8) installed upstream of *water coil inlet* to collect foreign material which would clog the flow valve orifice.

The figure shows the use of shutoff valves (4) and (5), on the in and out water lines to permit isoation of the unit from the plumbing system should future service work require this. Globe valves should not be used as shutof valves because of the excessive pressure drop inherent in the valve design. Instead, use either gate or ball valves as shutoffs, so as to minimize pressure drop.

Hose bib (6) and (7), and tees should be included to permit acid cleaning the refrigerant-to-water coil should such cleaning be required. See **WATER CORROSION**.

**Hose bib** (1) provides access to the system to check water flow through the constant flow valve to ensure adequate water flow through the unit. A water meter is used to check the water flow rate.

#### **WELL PUMP SIZING**

Strictly speaking, sizing the well pump is the responsibility of the well drilling contractor. It is important, however, the HVAC contractor be familiar with the factors that determine what size pump will be required. Rule of thumb estimates will invariably lead to under or oversized well pumps. Undersizing the pump will result in inadequate water to the whole plumbing system, but with especially bad results to the heat pump - NO HEAT/NO COOL calls will result. Oversized pumps will short cycle and could cause premature pump motor or switch failures.

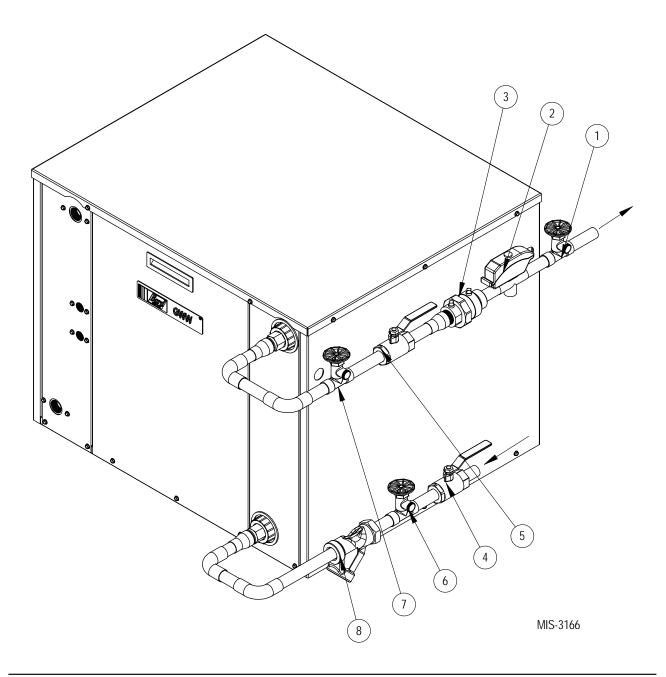

The well pump must be capable of supplying enough water and at an adequate pressure to meet competing demands of water fixtures. The well pump must be sized in such a way that three requirements are met:

- 1. Adequate flow rate in GPM.
- 2. Adequate pressure at the fixture.
- 3. Able to meet established flow rates and pressures from the depth of the well-feet of lift.

The pressure requirements put on the pump are directly affected by the diameter of pipe being used, as well as the water flow rate through the pipe. The worksheet included in Manual 2100-078 should guarantee the well pump has enough capacity. It should also ensure that the piping is

not undersized, which would create too much pressure due to friction loss. High pressure losses due to undersized pipe will reduce efficiency and require larger pumps and could also create water noise problems.

FIGURE 7
WATER CONNECTION COMPONENTS

#### SYSTEM START UP PROCEDURE FOR **GROUND WATER APPLICATIONS**

- 1. Be sure main power to the unit is OFF at disconnect.
- 2. Set thermostat system switch to OFF.
- 3. Move main power disconnect to ON. Except as required for safety while servicing – DO NOT OPEN THE UNIT DISCONNECT SWITCH.
- 4. Fully open the manual inlet & outlet valves, and manually open water solenoid valve on the source side.
- 5. Check water flow.

opened.

- a. Connect a water flow meter to the drain cock between the constant flow valve and the solenoid valve. b. Check the water flow rate through the constant flow valve and the solenoid valve. Run a hose from the flow meter to a drain or sink. Open the drain cock. c. When water flow is okay, close the drain cock and remove the water flow meter. The unit is now ready
- 6. Start the unit in heating mode by switching on the Aquastat. a. Make sure the water solenoid valve actuated/
- 7. Check the system refrigerant pressures against the refrigerant pressure table located on the backside of the system service door at the corresponding source and load flow rates and enetering water temperatures. If the refrigerant pressures do not match, check for water flow issues, and then a refrigeration system problem.
- 8. Switch the Aquastat/thermostat to cooling mode and again verify water solenoid actuation, and refrigerant pressures.

**NOTE:** *If a charge problem is determined (high or low):* 

- A. Check for possible refrigerant loss.
- B. Reclaim all remaining refrigerant.
- C. Evacuate unit down to 29" of vacuum.
- D. Recharge unit with refrigerant by weight to the serial plate, as this is the only way to ensure proper charge.

#### WATER CORROSION

Two concerns will immediately come to light when considering a water source heat pump, whether for ground water or for a ground loop application: Will there be enough water? And, how will the water quality affect the system?

Water quantity is an important consideration and one which is easily determined. The well driller must perform a pump down test on the well according to methods described by the National Well Water Association. This test, if performed correctly, will provide information on the rate of flow and on the capacity of the well. It is important to

consider the overall capacity of the well when thinking about a water source heat pump because the heat pump may be required to run for extended periods of time.

The second concern, about water quality, is equally important. Generally speaking, if the water is not offensive for drinking purposes, it should pose no problem for the heat pump. The well driller or local water softening company can perform tests which will determine the chemical properties of the water.

Water quality problems will show up in the heat pump in one or more of the following ways:

- Decrease in water flow through the unit.
- Decreased heat transfer of the water coil (entering to leaving water temperature difference is less).

There are four main water qualtiy problems associated with ground water. These are:

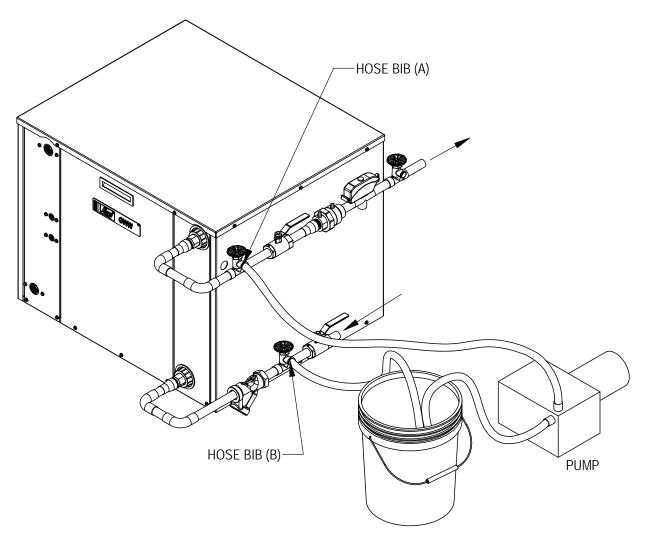

- 1. **Biological Growth** This is the growth of microscopic organisms in the water and will show up as a slimy deposit throughout the water system. Shock treatment of the well is usually required and this is best left to the well driller. The treatment consists of injecting chlorine into the well casing and flushing the system until all growth is removed.
- 2. Suspended Particles in the Water Filtering will usually remove most suspended particles (fine sand, small gravel) from the water. The problem with suspended particles in the water is it will erode metal parts, pumps, heat transfer coils, etc. As long as the filter is cleaned and periodically maintained, suspended particles should pose no serious problem. Consult with your well driller.
- 3. **Corrosion of Metal** Corrosion of metal parts results from either highly corrosive water (acid water, generally not the case with ground water), or galvanic reaction between dissimilar metals in the presence of water. By using plastic plumbing or dielectric unions, galvanic reaction is eliminated. The use of corrosion resistant materials such as a Cupronickel Water Coil through the water system will reduce corrosion problems significantly.
- 4. Scale Formation Of all the water problems, the formation of scale by ground water is by far the most common. Usually due to the formation of calcium carbonate, but magnesium carbonate or calcium sulfate may also be present. Carbon dioxide gas (CO2), the carbonate of calcium and magnesium carbonate, is very soluble in water. It will remain dissoved in the water until some outside factor upsets the balance. This outside influence may be a large change in water temperature or pressure. When this happens, enough carbon dioxide gas combines with the dissolved calcium or magnesium in the water and falls out of solution until a new balance is reached. The change in temperature that this heat pump produces is usually not high enough to cause the dissoved gas to fall out of solution. Likewise, if pressure drops are kept to a reasonable level, no precipitation of carbon dioxide should occur.

#### **REMEDIES OF WATER PROBLEMS**

**Water Treatment.** Water treatment can usually be economically justified for water loop systems. However, because of the large amounts of water involved with a ground water system, water treatment is generally too expensive.

Acid Cleaning the Water Coil or Heat Pump Recovery Unit. If scaling of the coil is strongly suspected, the coil can be cleaned with a solution of Phosphoric Acid (food grade acid). Follow the manufacturer's directions for mixing, use, storage, etc. Refer to the "Cleaning Water Coil", Figure 8. The acid solution can be introduced in the heat pump coil through the hose bib A. Be sure the isolation valves are closed to prevent contamination of the rest of the system by the coil. The acid should be pumped from a bucket into the hose bib and returned to the bucket through the other hose bib B. Follow the manufacturer's directions for the product used as to how long the solution is to be circulated, but it is usually circulated for a period of several hours.

## FIGURE 8 WATER COIL CLEANING

MIS-3167

#### LAKE AND POND INSTALLATIONS

Lakes and ponds can provide a low cost source of water for heating and cooling with a ground water heat pump. Direct usage of the water without some filtration is not recommended as algae and turbid water can foul the water to refrigerant heat exchanger. Instead, there have been very good results use a dry well dug next to the water line or edge. Normal procedure in installing a dry well is to backhoe a 15 to 20 foot hole adjacent to the body of water (set backhoe as close to water's edge as possible). Once excavated, a perforated plastic casing should be installed with gravel backfill placed around the casing. The gravel bed should provide adequate filtration of the water to allow good performance of the ground water heat pump.

The following is a list of recommendations to follow when installing this type of system:

- A. A lake or pond should be at least 1 acre (40,000 square feet) in surface area for each 50,000 BTUs of ground water heat pump capacity or have 2 times the cubic feet size of the dwelling that you are trying to heat (includes basement if heated).
- B. The average water depth should be at least 4 feet and there should be an area where the water depth is at least 12 to 15 feet deep.
- C. If possible, use a submersible pump suspended in the dry well casing. Jet pumps and other types of suction pumps normally consume more electrical energy than similarly sized submersible pumps. Pipe the unit the same as a water well system.
- D. Size the pump to provide necessary GPM for the ground water heat pump. A 12 GPM or greater water flow rate is required on all models when used on this type system.

- E. A pressure tank should be installed in dwelling to be heated adjacent to the ground water heat pump. A pressure switch should be installed at the tank for pump control.
- F. All plumbing should be carefully sized to compensate for friction losses, etc., particularly if the pond or lake is over 200 feet from the dwelling to be heated or cooled.
- G. Keep all water lines below low water level and below the frost line.
- H. Most installers use 4-inch field tile (rigid plastic or corrugated) for water return to the lake or pond.
- I. The drain line discharge should be located at least 100 feet from the dry well location.
- J. The drain line should be installed with a slope of 2 inches per 10 feet of run to provide complete drainage of the line when the ground water heat pump is not operating. This gradient should also help prevent freezing of the discharge where the pipe terminates above the frost line.
- K. Locate the discharge high enough above high water level so the water will not back up and freeze inside the drain pipe.
- L. Where the local conditions prevent the use of a gravity drainage system to a lake or pond, instead run standard plastic piping out into the pond below the frost and low water level.

For complete information on water well systems and lake and pond applications, refer to Manual 2100-078 available through your distributor.

#### **DESCRIPTION**

The system is designed to heat domestic water using the heat recovered from a water source unit's hot discharge gas.

#### **LOCATION**

Because of potential damage from freezing or condensation, the unit must be located in a conditioned space, therefore the unit must be installed indoors. Locate the storage tank as close to the geothermal heat pump and pump module as the installation permits. Keep in mind that water lines should be a maximum of 25 feet long measured one way. Also, the vertical lift should not exceed 20 feet. This is to keep the pressure and heat losses to a minimum.

#### **ELECTRICAL CONNECTION**

The desuperheater logic control with the remote thermal sensors are built already hard-wired in the unit control panel (when purchased with desuperheater option). 208/230-60-1 power for the desuperheater pump is supplied with the same power as the compressor. The 24 volt signals needed are also tied in with the compressor call signals.

NEVER ALTER OR PLUG FACTORY INSTALLED PRESSURE RELIEF VALVE ON WATER HEATER OR AUXILIARY TANK

#### **INSTALLATION PROCEDURE - GENERAL**

Before beginning the installation, turn off all power supplies to the water heater and unit, and shut off the main water supply line.

**TWO TANK** – In order to realize the maximum energy savings from the heat recovery system, it is recommended that a second water storage tank be installed in addition to the main hot water heater. Fossil Fuel fired water heaters must be a two-tank installation.

Tanks specifically intended for hot water storage are available from water heater manufacturers (solar hot water storage tanks). A well insulated electric water heater without the electric heating elements will also make a suitable storage tank.

The size of the storage tank should be as large as space and economy permit but in no event should it be less than one-half of the daily water requirements for the occupants. As a guide in estimating the daily family water requirements, The Department of Energy recommends a figure of 16.07 gallons of hot water per day per individual. For example, a family of four would require 64.3 gallons per day (4 x 16.07).

ONE TANK – The single hot water tank may be a new hot water heater (sized to 100% of daily water requirements) or the existing water heater in the case of a retrofit installation. The existing water heater should be drained and flushed to remove all loose sediment. This sediment could damage the circulating pump. The bottom heating element should be disconnected.

**NOTE:** Make sure water heater thermostats are set below 125°F on **One Tank Unit**.

Water Piping - All water piping must adhere to all state and local codes. Refer to piping diagrams for recommended one and two tank installations. Piping connections are ½" nominal copper plumbing.

A cleanable "Y" type strainer should also be included to collect any sediment.

#### **OPERATION OF THE HEAT RECOVERY** UNIT

The pump module is a very simple device containing basic controls and a circulating pump. Heat is transferred from the hot refrigerant (discharge gas) to the cool water.

The operation of the Desuperheater Pump Module is controlled first by the operation of the Geothermal Heat Pump and secondly by internal controls with desuperheater logic control. A low voltage signal sent in tandem to the signal to energize the compressor contactor is connected to the desuperheater logic control board, and acts as the primary on/off switch for the circulating pump.

Also connected to this board is a temperature overlimit device which shuts down the desuperheater once inlet water has exceeded 125°F so the water cannot create a scald condition.

There are also two (2) thermistor sensors connected to the control board. These thermistors are measuring and controlling to ensure there is a positive heat differential across the water being circulated. When operating in Part Load Condition, there are certain conditions (source temperatures versus hot water temperatures) that potential exists where heat could transfer into the refrigeration system instead of the refrigeration system into the hot water. Through the control board logic, these thermistors ensure there is at least a 2° positive differential between entering/leaving water temperatures, and will shut down the pump accordingly.

#### START UP AND CHECK OUT

Be sure all shut off valves are open and all power supplies are on. Open a hot water faucet to permit any air to bleed from the plumbing.

**NOTE:** The inherent design of this pump for maximum efficiency means this pump is not self-priming. It is imperative to check the air has been adequately bled from the system. There is a bleed-port built into desuperheater coil water system that should be utilized after the household water system has been fully restored. The bleed port is located on the water-tube on the top of the desuperheater exchange coil (above cooling expansion valve in the GW-Series products).

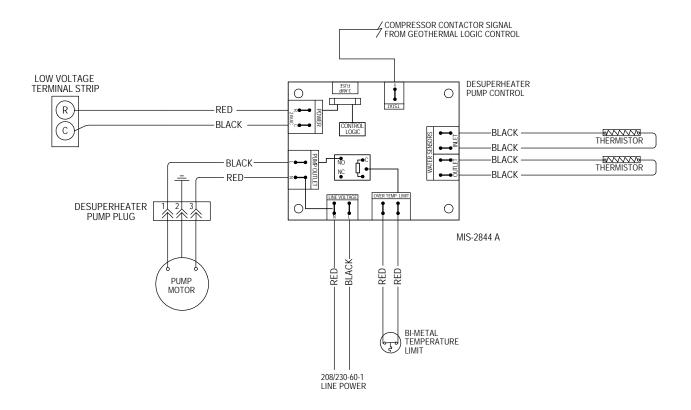

Turn ON the heat pump system and verify the circulating pump will operate. Feel the "WATER TO UNIT" and "WATER FROM WATER HEATER" tubes for noticable difference in temperature. Turn OFF the system and verify that the circulating pump stops.

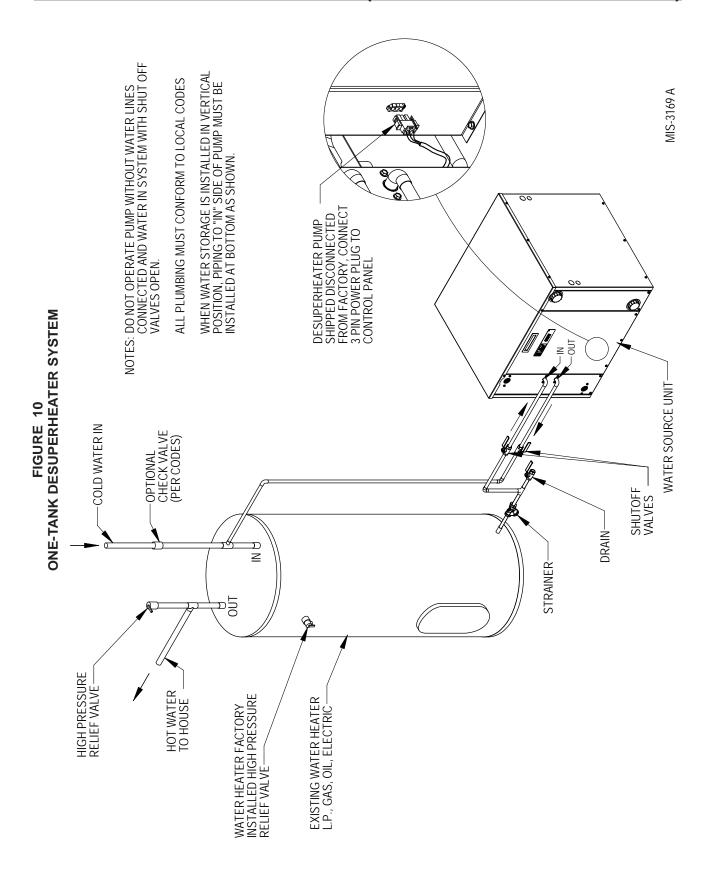

**NOTE:** When checking the refrigerant operating pressures of the ground source heat pump the desuperheater must be turned off. With the desuperheater operating, a wide variance in pressure can result, giving the service technician the indication there is a charge problem when the unit is operating correctly.

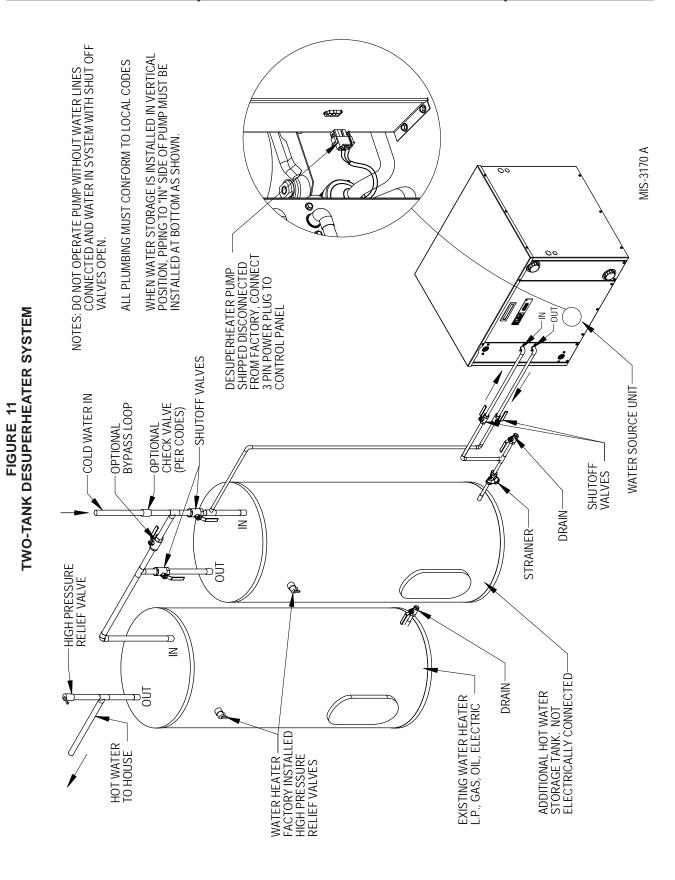

#### **MAINTENANCE**

**CLEANING THE HEAT EXCHANGER** – If scaling of the coil is strongly suspected, the coil can be cleaned with a solution of phosphoric acid (food grade acid or liquid ice machine cleaner {pre-mix phosphoric acid}). Follow the manufacturer's directions for the proper mixing and use of cleaning agent.

## FIGURE 9 DESUPERHEATER WIRING DIAGRAM

## DESUPERHEATER CONTROL BOARD SEQUENCE OF OPERATION

The desuperheating control board will make a determination whether or not to energize the pump relay inclusive on the control board.

- A. It will constantly monitor inputs from two temperature sensors, Inlet & Outlet water sensors.
- B. It will constantly monitor the "CC" Compressor Contactor Signal (only energized when compressor is operating).
- C. Upon acknowledgement of "CC" signal, and following two minutes, the control board will energize the pump relay.
- D. After 1½ minutes, based upon temperature difference between Outlet & Inlet sensors, and the presence of "CC" signal, the following will take place:

- If temperature difference is greater than 3°F, the control will continue to energize the pump relay.
- If temperature difference is less than 3°F, then the control will de-energize the pump relay.
- The control will next wait 10 minutes before repeating first bullet point.
- E. The Over Temperature Limit Switch is placed in series with line voltage. Therefore, continuity between "L" of line voltage and "L" of pump output is forced broken when the Over Temperature Limit Switch opens (see wiring diagram).
- F. The 3-amp fuse is put in series with the "R" connection to the board. Whenever the fuse is blown, the control board will lose power and consequently, the relay will disengage.

## **SEQUENCE OF OPERATION**

#### PART LOAD COOLING

When the thermostat system switch is placed in "COOL", it completes a circuit from "R" to "O", energizing the reversing valve solenoid. On a call for cooling, the thermostat completes a circuit from "R" to "Y1" sending the signal to the Geothermal Logic Control. The Geothermal Logic Control verifies that the High Pressure Switch, the Low Pressure Switch, and the Flow Switch control are all in the closed position. It then energizes the "A" terminal output to start the flow center (Ground Loop Applications) or energizes the water solenoid (Ground Water/Water Loop Applications). Following 10 seconds of the "A" terminal energization, the compressor contactor is energized.

#### **FULL LOAD COOLING**

The unit should already be operating in Part Load Cooling operation prior to Full Load Cooling being energized (see above). Additionally, what occurs, the thermostat completes a circuit from "R" to "Y2". This sends a signal to the compressor staging solenoid (plug on side of compressor).

#### PART LOAD HEATING

When thermostat is placed in "HEAT", the reversing valve solenoid is no longer energized. On a call for heating, the thermostat completes a circuit from "R" to "Y1" sending the signal to the Geothermal Logic Control. The Geothermal Logic Control verifies that the High Pressure Switch, the Low Pressure Switch, and the Flow Switch control are all in the closed position. It then energizes the "A" terminal output to start the flow center (Ground Loop Applications) or energizes the water solenoid (Ground Water/Water Loop Applications). Following 10 seconds of the "A" terminal energization, the compressor contactor is energized.

#### **FULL LOAD HEATING**

The unit should already be operating in Part Load Heating operation prior to Full Load Cooling being energized (see previous). Additionally, what occurs, the thermostat completes a circuit from "R" to "Y2". This sends a signal to the compressor staging solenoid (plug on side of compressor).

**GEOTHERMAL LOGIC CONTROL** – If the controller operates in normal mode, the Green Status Light blinks. This indicates that 24 volt power is applied to the board and the controller is running in normal operation.

On initial power up and call for compressor operation, a 5-minute delay + a random start delay of 0 to 60 seconds is applied. After the random delay, the compressor relay is energized (Terminal "CC"). When the "Y" input opens the compressor de-energizes.

**Water Solenoid** – When "Y" signal is sent to Geothermal Logic Control, the water solenoid output "A" terminal will energize 10 seconds prior to "CC" output that starts compressor.

**Anti-Short Cycle Timer** – After compressor shut-down, or power disruption, a 5-minute timer is applied and prevents the compressor from operating.

#### HIGH PRESSURE SWITCH

(Terminals HP1 & HP2) Circuit will be proved as "closed" prior to energizing "A" or "CC" terminals. If pressure switch opens, compressor will go into soft lockout mode and compressor operation will be terminated; green fault light illuminated. Logic control will then go through 5-minute delay on break + random start sequence. If no fault found on next run cycle, compressor will continue operation. If fault reoccurs, hard lockout occurs, and fault singal is sent to "L" terminal.

#### LOW PRESSURE SWITCH

(Terminals LP1 & LP2) Circuit will be proved as "closed" prior to energizing "A" or "CC" terminals. The condition of the LP terminals will then be ignored for the first 90 seconds after a demand for compressor operation. Following this 90 second period, if pressure switch opens, compressor will go into soft lockout mode and compressor operation will be termininated; orange fault light illuminated. The control board will then go through a 5-minute delay on break + random start sequence. If no fault found on next run cycle, compressor will continue operation. If fault recoccurs, hard lockout occurs, and the fault signal is sent to the "L" terminal.

#### **FLOW SWITCH**

(Terminals FS1 & FS2) Circuit will be proved as "closed" prior to energizing "A" or "CC" terminals. If either flow switch opens, compressor will go into soft lockout mode and compressor operation will be terminated; red fault light illuminated. Logic control will then go through 5-minute delay on break + random start sequence. If no fault found on next run cycle, compressor will continue operation. If fault reoccurs, hard lockout occurs, and fault signal is sent to "L" terminal.

#### **OVER & UNDER VOLTAGE PROTECTION**

When an an under or over voltage condition exists, the controller locks out the unit. When condition clears, the controller automatically releases the unit to normal operation and the compressor restarts after the random start and anti-short cycle timings are met. The under & over voltage protection starts at plus or minus 20% from nominal voltage and returns to operation at plus or minus 10% from nominal voltage. All four (4) LED fault lights will flash when an under or over voltage condition occurs. The over voltage protection can be disabled by removing the O/V jumper on the Geothermal Logic Control Board.

#### INTELLIGENT RESET

The Geothermal Logic Control has an intelligent reset feature after a safety control is activated. The controller locks out the unit for 5 minutes, at the end of this period. the controller checks to verify that all faults have been cleared. If faults have been cleared, the controller restarts the unit. If a second fault occurs, the controller will lockout the unit until the control is reset by breaking "Y" signal from thermostat. The last fault will be kept in memory after a full lockout; this is only cleared by cycling the unit power.

#### **ALARM OUTPUT**

The "L" terminal has 24 volts applied when a hard lockout occurs. This can be used to drive a fault light or a low voltage relay.

#### PRESSURE SERVICE PORTS

High and low pressure service ports are installed on all units so the system operating pressures can be observed. Pressure tables can be found later in this manual, and also applied to the backside of the service door of the unit. It is imperative to match the correct pressure table to the unit by model number, and to the correct conditions (temperature & flow rate). Also note that all pressure tables are without the desuperheater operational.

#### **CHECKING REFRIGERANT CHARGE** QUANTITY

The correct R-410A charge is shown on the unit rating plate. Reference Figure 17 – 21 to validate proper system operation. However, it is recommended that if incorrect charge is suspected, the system refrigerant charge be reclaimed, evacuated, and charge to nameplate charge quantity and type

The nameplate charge quantity is optimized for thermal performance and efficiency throughout all modes of operation.

## REFRIGERANT CHARGE

The models covered by this manual require R-410A refrigerant, and Polyol Ester refrigerant oil.

#### **GENERAL**

- Use separate service equipment to avoid cross contamination of oil and refrigerants.
- 2. Use recovery equipment rated for R-410A refrigerant.
- 3. Use manifold gauges rated for R-410A (800 psi high-side/250psi low-side).
- 4. R-410A is a binary blend of HFC-32 and HFC-125.
- R-410A is nearly azeotropic similar to R-22 and R-12. Although nearly azeotropic, charge with liquid refrigerant.
- 6. R-410A operates at 40-70% higher pressure than R-22, and systems designed for R-22 cannot withstand this higher pressure.
- R-410A has an ozone depletion potential of zero, but must be reclaimed due to its global warming potential.
- 8. R-410A compressors use Polyol Ester Oil.
- Polyol Ester is hydroscopic; it will rapidly absorb moisture, and strongly hold this moisture in the oil.
- 10. A liquid line dryer must be used even a deep vacuum will not separate moisture from the oil.
- 11. Limit atmospheric exposure to 15 minutes.
- 12. If compressor removal is necessary, always plug compressor immediately after removal. Purge with small amount of nitrogen when inserting plugs.

#### R-410A

#### REFRIGERANT CHARGE

This unit was charged at the factory with the quantity of refrigerant listed on the serial plate. AHRI capacity and efficiency ratings were determined by testing with this refrigerant charge quantity.

The following pressure tables show nominal pressures for the units. Since many installation specific situations can affect the pressure readings, this information should only be used by certified technicians as a guide for evaluating proper system performance. They shall not be used to adjust charge. If charge is in doubt, reclaim, evacuate and recharge the unit to the serial plate charge.

#### **TOPPING OFF SYSTEM CHARGE**

If a leak has occurred in the system, reclaiming, evacuating (see previous criteria), and charging to the nameplate charge is recommended.

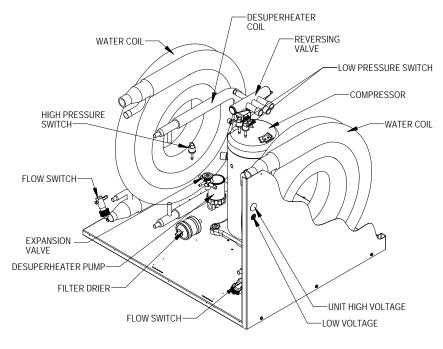

Topping off the system charge can be done without problems. With R-410A, there are no significant changes in the refrigerant composition during multiple leaks and recharges. R-410A refrigerant is similar to an azeotropic blend (it behaves like a pure compound or single component refrigerant). The remaining refrigerant charge, in the system, may be used after leaks have occurred and then "top-off" the charge by utilizing the charging charts on the service door of the unit or this manual as a guideline.

**REMEMBER:** When adding R-410A refrigerant, it must come out of the charging cylinder/tank as a liquid to avoid any fractionation, and to ensure optimal system performance. Refer to instructions for the cylinder that is being utilized for proper method of liquid extraction.

#### SAFETY PRACTICES

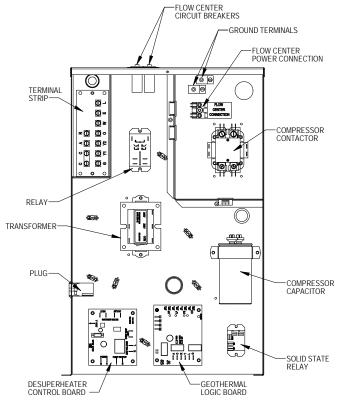

- 1. Never mix R-410A with other refrigerants.
- Use gloves and safety glasses, Polyol Ester oils can be irritating to the skin, and liquid refrigerant will freeze the skin.
- 3. Never use air and R-410A to leak check; the mixture may become flammable.
- 4. Do not inhale R-410A the vapor attacks the nervous system, creating dizziness, loss of coordination and slurred speech. Cardiac irregularities, unconsciousness and ultimate death can result from breathing this concentration.
- 5. Do not burn R-410A. This decomposition produces hazardous vapors. Evacuate the area if exposed.
- 6. Use only cylinders rated DOT4BA/4BW 400.
- 7. Never fill cylinders over 80% of total capacity.
- 8. Store cylinders in a cool area, out of direct sunlight.
- 9. Never heat cylinders above 125°F.
- 10. Never trap liquid R-410A in manifold sets, gauge lines, or cylinders. R-410A expands significantly at warmer temperatures. Once a cylinder or line is full of liquid, any further rise in temperature will cause it to rupture or burst.

#### **SERVICE HINTS**

Check all power fuses or circuit breakers to ensure that they are all the correct rating.

#### **UNBRAZING SYSTEM COMPONENTS**

If the refrigerant charge is removed from a scroll equipped unit by bleeding the high side only, it is sometimes possible for the scrolls to seal, preventing pressure equalization through the compressor. This may leave low side shell and suction line tubing pressurized. If the brazing torch is then applied to the low side while the low side shell and suction line contain pressure, the pressurized refrigerant and oil mixture could ignite when it escapes and contacts the brazing flame. To prevent this occurence, it is important to check both the high and low side system pressures with manifold gauges before unbrazing. Removal of service port cores is highly recommended as secondary insurance that all system pressure has been relieved.

#### **COMPRESSOR SOLENOID**

See Sequence of Operation on Pages 28 & 29 for function.

A nominal 24-volt direct current coil activates the internal compressor solenoid. The input control circuit voltage must be 18 to 28 volts ac. The coil power requirements is 5 VA. The external electrical connection is made with a molded plug assembly. This plug contains a full wave rectifier to supply direct current (dc volts) to the unloader coil.

#### COMPRESSOR SOLENOID TEST PROCEDURE

– If it is suspected that the unloader is not working, the following methods may be used to verify operation.

- Operate the system and measure compressor amperage. Cycle the compressor solenoid on and off at 10-second intervals. The compressor amperage should go up or down at least 25 percent.
- If Step #1 does not give the expected results, shut unit off. Apply 18 to 28 volts ac to the solenoid molded plug leads and listen for a click as the solenoid pulls in. Remove power and listen for another click as the solenoid returns to its original position.
- 3. If "clicks" cannot be heard, shut off power and remove the control circuit molded plug from the compressor and measure the solenoid coil resistance. The resistance should be 32 to 60 ohms depending on compressor temperature.
- 4. Next, check the molded plug:

**Voltage Check:** Apply control voltage to the plug wires (18 to 28 volts ac). The measured dc voltage at the female connectors in the plug should be around 15 to 27 volt dc.

Resistance Check: Measure the resistance from the end of the one molded plug lead to either of the two female connectors in the plug. One of the connectors should read close to zero ohms, while the other should read infinity. Repeat with other wire. The same female connector as before should read zero, while the other connector again reads infinity. Reverse polarity on the ohmmeter leads and repeat. The female connector that read infinity previously should now read close to zero ohms. Replace plug if either of these test methods does not show the desired results.
